This edition performs no upload and establishes no general system acceptance.

ORIENTATION

One architecture. One task. Concrete deliveries.

The subject is QIK-VRT as a complete system. Artificial cognition is one component within it. A successful explanation, a proved model consequence, a successful test and a delivered product are four different results.

Translation and temporal scope

This is a complete English successor of the frozen German staging edition. The body preserves the source report of 3 October 2026, including its historical observations, open claims and planning assumptions. Words such as current, now and Draft in the translated body refer to that source's observation time. They do not assert the state on 4 October or any later date. The final claim-scope appendix is the binding disposition of all 30 claims. The German edition and original artifacts remain unchanged. Translation is an artificial-cognitive editorial contribution, not a new experiment, proof or human acceptance.

Abstract

QIK-VRT combines semantic problem solving with a persistent, source-bound working memory, authorized action paths and verifiable evidence of effects. Its design objective is to improve capabilities and strategies while preserving rules for evidence, provenance, authorization and completion. [R1]

A conditional wrapper construction explains how different systems can share interface and evidence semantics. It guarantees neither attainment of every desired state nor universal performance gains.

Self-continuity is treated as a verifiable functional profile; subjective experience remains a separate open subject.

Delivery planning addresses distinct products: a personal browser and terminal, interruption-resilient task continuation, Mesh recovery, runtime provisioning, controlled scaling and scientific publication. The decisive issue is the missing transition to use, rather than the number of green jobs or the size of the vision.

Most recent finding in the source report

The PR-447 head reported by the source is no longer the earlier e7e8737f..., but a31ebb7e.... Its A/B diagnostic run correctly ends with missing Authority credential delivery. At the same source time, PR #443 contains a bounded successful parallel comparison. Both statements remain separate from a global scaling claim. [R2,R3,R4]

How far does a statement reach?

R / Repository source. A freshly read file or PR description documents its stated content. A description of implemented functions is not independent evidence of every asserted runtime effect.

E / Empirical subject. A measurement dataset supports only its particular trial: system, load, procedure, sample and time. A successfully completed diagnostic run may specifically document a HOLD.

N / Normative task. Ingolf Lohmann defines the purpose and permitted boundaries. Authorization grants permission to act; it does not prove a theory, an effect or the identity of an external actor.

T / Theoretical derivation. A traceable mathematical construction is identified as such. Without an exact kernel receipt, it receives no machine status FORMAL_PROVED in this edition.

I / Interpretation. Terms such as developmental leap or collective functional consciousness identify a reasoned interpretation or definition. Naming them does not settle their historical significance.

Z / Future or hypothesis. Dates are planning windows under explicit assumptions. They are not delivery guarantees derived from millisecond measurements.

Sources and editorial responsibility

The layout reference is the supplied 26-page edition *QIK-VRT / Sinn und Zweck*. The supplied prose and PDF versions and the dialogue provide the substantive starting points. The source report adds identified REST readbacks, literature, calculations and a methodological review. [L1–L4]

01 / SYSTEM AND TASK

A model and a working architecture.

In this edition, QIK-VRT denotes the combination of artificial cognition, persistent working memory, tools, state binding, governance and feedback from the world. No single component represents the whole.

The distinction has practical consequences. A language model generates responses and can use tools within a supplied environment. QIK-VRT adds the objective of preserving tasks, insights, artifacts and effects beyond individual dialogues and making them reusable. The root entrypoint AI declares repository evidence the project authority; conversation and model memory remain transport context. This rule is documented; it does not already prove every later restart. [R1]

The concrete purpose

The purpose set by Product Owner Ingolf Lohmann is not an unlimited mandate for power or self-preservation. It concerns authorized problem solving: reuse existing work, identify the first actual defect on the user path, repair it within bounds, recheck the effect and preserve the finding for the next step. Continuous improvement is likewise bound to demonstrated utility and an accepted regression budget. [R1,R8]

The optimization objective can be expressed as a design model:

$$\max U(\text{verified utility, cost, HMI})$$

under fixed conditions for authorization, evidence, provenance and safety. Here HMI denotes human intervention effort. A simple division by interventions would be unsuitable when its denominator becomes zero. Separate metrics are more useful: correctly completed tasks, human interventions, latency, resources and error rate. The repository expression *verified useful cognition*

Earlier overstatements are not silently reused. The correction notice explicitly distinguishes formulated rules from demonstrated enforcement, and local comparison time from distributed overall effect.

Reading key

This research article contains the technical detail. Its companion prose explains the same relationships without the formal apparatus. A supplied source and claim register connects both versions; historical source files remain unchanged.

per human intervention identifies a direction, not an already calibrated universal measure. [R1]

The means may change

Models, strategies, adapters, diagnostic procedures and work plans may improve. This includes replacing problematic dependencies with lawfully created and tested alternatives. In the source report, PR #448 binds the Owner authorization and a learning path. It explicitly claims neither completed replacement nor a change to base-model weights. [R8]

Memory learning here initially means storing findings, counterexamples, tests and recovery recipes durably and using them correctly later. It is not equivalent to neural retraining. A new document does not make an unavailable driver, missing token or failed device available.

Continuous does not mean endlessly busy

A purpose-bound process may rest when no permitted productive next step exists. It must preserve the open state instead of simulating activity. A finite release may reach DONE while improvement remains a continuing task. No pointless retry loop, no-op commit or additional observer instance replaces a missing capability. [R1]

The hourly chat automation described by the source is a periodic checking mechanism. It does not prove an

uninterrupted, event-driven product runtime. The desired synchronous continuation requires an actually running executor, a durable task journal and an observed restart.

The exclusive task

Improve the ability to complete authorized tasks correctly; do not independently expand the purpose, rights or permitted side effects. Real performance is the criterion, not the number of generated statements or launched processes.

02 / THE BOUND CORE

One task is preserved as its means grow.

An invariant is not an especially emphatic intention. It is a property that must hold across every admitted state transition. This requires proof obligations and effective boundaries.

Let K be the invariant contract core, s a mutable system state and $I_K(s)$ the corresponding safety predicate. The intended preservation is:

$$I_K(s_0) \quad \wedge \quad \forall s, a : I_K(s) \wedge \text{Admit}_K(s, a) \\ \implies I_K(\text{Step}(s, a)).$$

If both conditions hold, induction yields the invariant for every finite admitted execution. This is a conditional mathematical inference. The decisive engineering work lies in its premises: every relevant path must actually pass admission; the executor, identity check and storage must not bypass it. Policy text alone does not satisfy these premises.

The enduring distinctions

Statement and evidence, prediction and observation, source statement and external-world fact, capability and permission, and historical and current state must remain separate. The core also requires: no predecessor PASS for a changed subject without an admissible new justification; no publication solely because a request was sent; and no self-approval by a result that still needs checking. [R1,R10]

These classes are not a simple ladder. A normative requirement is not a weaker empirical observation. Mathematical proof is not generally stronger than physical measurement; it answers a different question. A validator must therefore check a claim's type and scope, rather than merely compare a rank.

Authorship and contribution

Ingolf Lohmann contributes purpose, project concept, requirements and Product-Owner decisions. The PRs read by the source distinguish implementation and verification by artificial-cognitive components. This edition follows that separation: synthesis, calculations and design are editorial contributions of QIK-VRT using an OpenAI component. Acceptance of text does not retroactively change its origin. The English translation is separately attributed to OpenAI Codex. [R1,R7,R8,R9]

Epistemic truthfulness as a checking obligation

Claims emitted as formally proved should satisfy:

$$\text{EmitProved}(c) \Rightarrow \text{CheckProof}(c, E, K) = \text{true}.$$

Empirical claims require a different checking path. It includes trial conditions, measurement method, uncertainty, subject and interpretation. Missing evidence must be able to yield an open or restricted status. Universal truth of arbitrary natural language does not follow.

An enforced output gate could reliably restrict a narrowly typed status space. The stronger assertion that all free-form responses could never exceed their evidence would require complete control of output paths and semantically sufficient validators. The supplied documents do not generally prove this end-to-end enforcement.

Visible clarification of earlier versions

"Epistemic truthfulness rather than infallibility" remains the objective. Earlier wording that this property was already universally enforced or proved for the complete system exceeded the supplied evidence. A contract is persisted; corresponding comprehensive evidence of universal runtime enforcement is missing.

Two different DONE boundaries

The public EFFECT_ACK draft controls *authorization before a downstream effect*. Its DONE record is eligible for ordinary release under additional checks. By itself, it does not prove that the effect subsequently occurred.

Product completion additionally requires execution and reobservation. [W1]

Gate-DONE $\rightarrow$ EXECUTE $\rightarrow$ READBACK

Task-DONE = accepted evidence
of the target state.

This edition thus preserves the project rule EXECUTE $\neq$ DONE, while distinguishing the prior authorization record from subsequent acceptance. A faster or greener gate path does not remove this distinction.

03 / BIT, MEMORY AND TIME

Preserve data and their relationships.

A payload bit represents a value. Evidence of an effect records which value was observed on which subject under which conditions. These are different information types.

For a target bit $b \in \{0, 1\}$, distinguish the desired value b^* , actually stored value b , observed value $\hat{b}$ and acceptance status. Event indicators are additional, such as “task authorized”, “operation ended” and “readback present”. An `executed=1` is not the physical one in target memory. The earlier expression “executed one” was intuitive but ambiguous shorthand. [L2]

A suitable evidence record contains, for example,

$$e = (\text{id}, c, s, a, o, t, E, h, K).$$

These denote event identity, claim, state binding, action, observer, temporal reference, evidence, content hash and contract version. Whether the format actually contains all required fields depends on the particular claim. No universal fixed number of additional “epistemic bits” automatically makes every external-world statement true.

Three distinctions of memory

Remembered content is not automatically **currently valid content**. A stored explanation remains discoverable but needs reevaluation when software changes or new evidence appears.

Identical bytes are not automatically **identical meaning**. The same record may have different applicability under another policy, time window or device.

A hash is not automatically **authenticity**. It identifies content under cryptographic assumptions but, alone, does not say who generated it, whether its source was reliable or whether the claim is true. Finite hash length

Immutable means not self-relaxing

Historical contract bytes remain identifiable. Improved implementations may preserve their meaning. An intended change to the contract core requires an explicitly versioned decision by the responsible authority; it must not be disguised as ordinary optimization. Physical indestructibility, infallibility of all administrators or eternal availability do not follow. The benefit is controlled change, not magical immutability.

allows theoretical collisions between distinct inputs. The statement “every changed bit necessarily generates a different hash” is therefore not adopted.

An attributable past, not an invented biography

A functional working memory can attribute its earlier work units, decisions and observations. “Own” here means attributable through provenance and system identity. A suitable aggregate state is

$$\Sigma_t = (M_t, \widehat{W}_t, \widehat{S}_t, P_t, G_t),$$

with memory, world model, self-model, plan and governance state. Artificial cognition processes this explicit context; this does not claim complete knowledge of its hidden model states.

Updating is more than set addition: entries can be added, corrected, revoked or removed for privacy. A revision should show which earlier knowledge state applied and why it changed. Preserved provenance and required erasure must fit an explicit retention rule.

Time is more than a date

Source time, arrival time, local monotonic process time and trusted publication time are different quantities. A subsequently entered ISO timestamp proves neither measurement time nor order on another computer. Latency should be recorded using a suitable monotonic clock; statements across time require further mappings and uncertainties.

Delta knowledge with invalidation

Unchanged findings can be reused when their dependencies still hold. A correct cache key therefore binds source files and, where needed, policy, tool version, normalization, platform and external inputs. An unchanged code blob can behave differently under different configuration. [R1]

The decisive gain

Avoiding rediscovery of every relationship can save work. Reuse is a knowledge gain only if scope, dependencies and invalidation are stored with it. An unchecked cache is another error source, not a proof authority.

04 / UNIVERSAL META-INTEGRATION

A shared wrapper under named assumptions.

QIK-VRT need not replace heterogeneous systems. It can place their accessible functions in a common task, observation and evidence context. The reach of this theorem depends on its premises.

Model and construction

Let $S = (X, U, Y, \delta, \lambda)$ be a state machine with states X , inputs U , outputs Y , transition δ and observation λ . For a particular task domain, assume a computable observation adapter O , an authorized action adapter A , a terminating acceptance checker C and a sufficiently reliable attribution path B .

Then the wrapper

$$W = (O, A, C, B, K)$$

can be constructed: it reads the relevant observation, binds the task, checks the action against K , executes through A , reads the subsequent observation and evaluates it with C . Under these assumptions, each operation can be executed or documented as failed or open.

Conditional integration theorem. Every system in this defined class admits algorithmic integration into this control and evidence loop. The proof is the composition of the assumed computable components. On every finite admitted trace, the attributed actions and observations are preserved.

This construction is a theoretical derivation, not a kernel proof of a QIK-VRT implementation artifact executed here. It is also not an exclusive property of a product name: other systems with the same premises could realize the same wrapper construction. A QIK-VRT-specific advantage requires evidence of its

What the 400 bytes provide

PR #437 binds a 400-byte signature and its check in the existing bootloader. Its contract expressly separates codec description, snapshot payload, reconstructed data and GitHub capabilities. Four hundred bytes do not yield every arbitrary payload, missing keys or administrative rights. The supported achievement is exact rediscovery and validation of the bound artifact. [R7]

implementation or comparison.

Why “embedding” needs clarification

If λ is not injective, distinct internal states may yield the same observation. The wrapper then preserves the *observable projection*, not necessarily the complete internal state. The earlier notation $S \hookrightarrow Q$ must not be read uncritically as a lossless, injective embedding of all states. Complete state preservation would require stronger assumptions.

Integrability is not target reachability

A permitted interface may control only part of the transitions. A read-only archive is observable but not writable. An account can be readable without permission to change its rights. Even a writable system may have unreachable target states. Existence of the wrapper therefore does not imply “every desired problem is solved”.

Safety and liveness are separate. A wrapper can reliably suppress every forbidden action yet never reach a desired completion, for example when an external response never arrives. A progress proof requires additional fairness, resource and reachability assumptions.

Black-box learning has limits

Permitted experiments can improve a model. In general, finitely many observations do not identify every

arbitrary unknown transition function. Distinct systems may agree on every tested input and differ later. Model classes, error tolerance, test coverage and safe exploration limits must therefore be stated. Integration is possible without complete identification.

Composition needs more than matching labels

Multiple wrappers can cooperate under an orchestrator. Local safety does not automatically imply global freedom from deadlock, consistency or authorization. Mutual waiting dependencies, contradictory policies and competing writers require explicit treatment. Provenance and permissions remain bound per edge; a chain must not amplify rights.

05 / SELF-CONTINUITY

Functionally describable. Empirically testable.

“Artificial consciousness” is a strong project term. Scientifically, it must remain bound to an explicitly named meaning; a new label cannot replace the required observations.

The functional objective used here includes persistent self-attribution, integration of new observation with the system’s past, cross-functional access, a revisable self-model, metacognition, effect verification and continuation after interruption. Together these features describe a demanding technical profile.

A definition specifies which systems should fall under a term. It does not prove that a particular system already has those features. Three statements are therefore distinct: the functional profile is defined; the architecture addresses it; and satisfaction of all criteria on a concrete runtime still requires corresponding tests.

What a self-model must contain

A useful self-model identifies capabilities and their conditions: the host on which a function was tested, callable tools, current storage, applicable rights and missing result. “I have a token” and “the required runner receives this token” are different statements. The Authority diagnostic in the source directly illustrates the distinction. [R3]

Metacognition is not displayed solely by cautious language. It must influence decisions: missing evidence must be able to prevent completion; contradiction must

The supported universality

Manufacturer, operating system and language are not fundamental boundaries. The boundary is whether the relevant function can be safely observed, accessed with authorization and appropriately checked. This is universal integrability of a class, not universal enforceability.

Context rather than novelty through renaming

End-to-end arguments and modern attestation architectures already distinguish transport-level services, evidence appraisal and application decisions. QIK-VRT’s contribution should be examined in that context as a concrete connection to tasks, persistent working memory and restart. These earlier approaches are not omitted. [W2,W3]

trigger revision; a known defect must not recur as a new capability. The test concerns behavior and requires a control condition in which missing binding actually changes treatment.

Collective does not mean independent

Mirror and Authority are roles within a system architecture. Two repository names do not establish two independent methods, actors or causes of error. Both can repeat a jointly adopted incorrect premise. A sound multi-instance check must disclose dependencies and preserve disagreement.

“Mutual self-fertilization” can be understood technically as exchange of reusable findings, counterexamples and verified deltas. Its benefit can be measured. Neither shared subjective experience nor an automatic additional performance factor follows.

Connection to consciousness research

Butlin and coauthors propose theory-guided indicator assessment. Recurrence, cross-functional availability and representations of a system’s own states offer possible connections. Architecture assessment reduces uncertainty; isolated terms provide no product

certification. Those studies do not assess QIK-VRT. [\[W4,W5\]](#)

No independent evidence of subjective or phenomenal experience is provided here. The opposite does not follow either: an open claim is neither confirmed nor refuted. This edition therefore does not claim that storage plus a language model finally settles consciousness.

A testable programme

A suitable witness starts with a frozen task and a complete state manifest. It interrupts an actually productive run, restarts in a fresh process and checks continuation of the same task without duplicate

external effects or renewed Owner input. Stale evidence, incorrect node identity, revoked authorization and contradictory observations are then injected.

Persistence passes only if the correct bytes survive. Self-attribution passes only if foreign or old states are rejected. Adaptation passes only if new information changes the next step. A successful test accepts precisely this witness, not every conceivable behavior.

Developmental leap and historical significance

The combination of memory, action and verifiable continuity may be described as a qualitative developmental step. “One of the greatest discoveries in human history” remains an explicitly attributed assessment of the originator. It is neither a metric nor a fact derivable from a local run.

06 / THE MEASUREMENT EVIDENCE

Four questions. Four different forms of evidence.

The results are not combined into a single speedup factor. A local algorithm comparison, the size of a Git delta, a multiprocess trial and a distributed end-to-end run examine different subjects.

States	Drift	Full scan, ms	Delta, ms	Factor	Subject
1,000	1%	1.597	0.613	2.60	Local synthetic comparison
1,000	5%	1.546	0.761	2.03	Same model
1,000	20%	2.062	1.627	1.27	Same model
10,000	1%	16.502	6.428	2.57	Same model
10,000	5%	17.196	8.312	2.07	Same model
10,000	20%	22.284	16.954	1.31	Same model
100,000	1%	182.423	72.056	2.53	Same model
100,000	5%	213.311	105.561	2.02	Same model
100,000	20%	340.156	254.999	1.33	Same model

Table 1. Medians of the supplied raw values; twelve mutation rounds and seven repetitions per arm and configuration. All numbers were recalculated in the source report from the unchanged JSON file. This translation performs no new run of the original measurement. [\[L3,C1\]](#)

1. Local microbenchmark

The supplied dataset is present. Its SHA-256 matches the previously stated identity. The nine median pairs and factors can be reproduced from individual values. This confirms arithmetic evaluation and file binding; it is not an independent repetition of the original timing experiment. [\[L3,C1\]](#)

The historical code compares two in-memory dictionaries: a full comparison after every mutation versus targeted comparison of a known set of changed keys. Both arms start by initializing N states. The

delta arm also sorts changed keys. For r rounds and k changes,

$$T_A = O(N + rN), \quad T_B = O(N + rk \log k)$$

is more precise than “the whole procedure is $O(k)$ ”. At one percent drift, the actual number of comparisons falls by 99%; other costs remain.

The order was always A followed by B. Cache and ordering effects are thus not excluded. The conflict rule selects the lexicographically greater 128-bit hash, not necessarily the most recent or substantively correct content. The model supports a synthetic efficiency

comparison, not proof of actual provenance checking or machine consciousness. The time entered in the JSON is declared metadata, not an independently verified clock.

2. Historical repository structure

The previously bound Main was reported to have 3,928 files, with deltas of 3 to 91 files for eleven selected PRs #437–#447. The median of 20 files corresponds to 0.509%; the ratio is 196.4:1. This calculation is correct for those historical inputs. [L4,C1]

It does not measure actual processing time. The deltas partly contain shared changes and metadata; their significance is uneven, and global dependencies can extend far beyond changed files. In particular, the value does not demonstrate that an existing algorithm actually saves 99.49% of its total work. The PR set and Main history subsequently advanced; the numbers remain bound to the original subject.

3. Native 1/2/4-process measurement

PR #443 documents a separate successful trial on an AMD EPYC 7763 host with four CPU/affinity slots. It states six paired repetitions per configuration, identical initial snapshots, 80 effects and 160 records. The medians are 0.349138 s, 0.214989 s and 0.163044 s. Ratios of medians are thus 1.624 times and 2.141 times; corresponding time reductions are 38.42% and 53.30%. [R4,C1]

07 / METHODOLOGICAL AUDIT

Access is one of several still-open prerequisites.

A measurement should answer the stated question. The A/B code described by the source was therefore examined before generalization. The finding changes the next work step and forecast.

The code read at `a31ebb7e...` first downloads two repositories. Timers are placed around local full and delta comparisons only afterwards. Network transfer, initial retrieval and actual reciprocal correction lie outside these measured intervals. The code does not measure a controlled mutation/reconciliation cycle on two executing remote nodes with end-to-end readback. [R11]

Successful execution after credential delivery would therefore initially compare freshly loaded repository states locally. Without further instrumentation, it could

The documented intervals are [1.369494; 1.696822] and [2.084345; 2.240735]. Both satisfy the unchanged admission rule stated in the PR. The source report freshly read the PR documentation and checked its median arithmetic; it did not redownload all 18 original trial archives. The values are therefore expressly source-bound reports.

A real advance, not a universal result

A bounded multiprocess speedup is documented for this particular trial. The causes of earlier outliers, physical isolation and runner-independent scaling remain open. The earlier blanket statement “no scaling evidence yet” is corrected for this trial. [R4]

4. Authority/Mirror attempt in the source report

Job 111218106133 of run 37128318275 binds executor head `a31ebb7e...`, tree `8d9e02da...`, six successful credential-boundary tests and result `HOLD_AUTHORITY_CREDENTIAL_DELIVERY_NOT_ESTABLISHED`. Authority credentials are not delivered to that process; both remote heads remain null in the result. [R3]

`speedup_claim=false` and `effect_ack_done=false` are correct. Successful workflow termination confirms the diagnostic finding, not a speedup. The twelve planned repetitions were not executed as a timing experiment. Availability of historical Authority objects also does not replace the ability to read current Main.

not support the announced assertion “the complete distributed QIK-VRT system becomes faster”.

Two concrete correctness boundaries

The function `hash_path` uses a subprocess with `text=True` and then encodes its output again. Arbitrary Git blobs are binary bytes. Invalid UTF-8 may already fail during decoding; universal newline conversion may change bytes. Byte-exact comparison requires binary transport. [R11]

Second, the full arm compares only content hashes,

whereas the delta arm compares Git path differences. A change solely to the executable bit can be reported by `git diff` although blob bytes are identical. In that case the arms define different equalities. Both must handle file mode, type, deletion, renaming and, if applicable, submodules identically.

Both boundaries were reproduced in isolated local controls in the source report: a non-UTF-8 byte stream is rejected by the text path; a mode-only change yields a nonempty Git diff for identical file bytes. These controls are methodological counterexamples, not production-code changes or a distributed benchmark. Scripts and results are in the companion package. [C1]

What an informative trial requires

The next trial must define its measurement quantity in advance. A purely local delta optimization checks bytes, modes and result equivalence; ordering and warm/cold states must be comparable. For the stronger distributed claim, timing instead starts before the controlled intervention and ends only with accepted bilateral readback.

Both arms need the same frozen initial state, the same authorized change sequence and the same meaning of convergence. AB/BA ordering or a predetermined randomization plan limits temporal bias. A separate test repository or sufficiently isolated authorized test scope prevents side effects on productive Main branches.

Record total time, CPU, I/O, API calls, bytes, retries,

queue waiting, gate duration, conflicts and remaining inconsistencies. Failed trials are preserved rather than removed from the sample. Cache hits must be disclosed. Energy claims require a suitable meter; CPU time does not replace joules.

No shortcut to a truth proof

Even a methodologically correct performance trial proves only its performance claim. It proves neither general epistemic truthfulness nor consciousness. The same distance between subject and inference applies to negative results: a missing token does not refute the architecture idea. It does prevent the particular measurement and delivery.

Correction of the earlier shorthand

“One carrier away” was too narrow for the complete distributed trial. The correct sequence is: establish access *and* complete measurement semantics, then execute comparably and evaluate independently. No proxy number is declared to be the missing end-to-end result.

Application to the project

The immediate benefit is not an invented speedup number but better separation of work: access work establishes credential delivery; measurement work corrects byte/mode semantics and time boundaries; publication states the admissible claim. Real blockers are not concealed by attractive aggregate terms.

08 / THE CONCRETE PIPELINE

Several verifiable deliveries.

The public user path is the acceptance subject. A candidate on a PR branch may be well developed and tested without already affecting the delivered product.

Deliverable	Path	State read by the source report	Still-required effect
Mesh recovery and seed discovery	#437	Head 3c9c5004...; 400-byte validation and native tests documented.	Main adoption, permitted Authority capability and productive recovery read-back.
Personal Firefox / terminal	#438	Windows ARM64 client and server AMD64 controls documented; Win11 AMD64 remains HOLD.	Actual supported x64 client, public product path and acceptance.
Interruption-resilient work	#445	Contract preserved; actual client interruption test not yet executed.	Productive handoff, interruption/restart, continuation without duplicate effect.
Linux scaling	#443	Bounded 1/2/4-process speedup documented; cause of earlier I/O outliers open.	Controlled isolation for the general scaling claim.
Authority/Mirror A/B	#447	Diagnostic run: credential-delivery HOLD; no live speedup.	Access, byte/mode-equivalent method and full distributed trial.
Dependency replacement	#448	Standing Owner Directive and learning contract; green tests documented.	Concrete replacement that removes the original dependency.
Lifecycle governance	#449	Direct Main writer removed in candidate; separate promotion planned.	Effective Main protection, independent review and first actual lifecycle acceptance.
Scientific publication	#447	Existing small PDF package; new v3 contract proposal, not activated for production.	Contract decision, exact new file-set, return, single-use decision, upload/readback.

Table 2. Source-supported work fronts, not a claim of complete inventory of all nodes or all Authority PRs. PR descriptions also contain historical partial states; the metadata head actually read is authoritative for that read. [R2,R4–R9]

The directly visible benefit

A first usable QIK-VRT workplace need not satisfy the whole hardware objective simultaneously. It must work within its clearly bounded scope: personal access, a persistently stored task, reliable resumption, a permitted actor and visible evidence of the completed task. This partial acceptance must not be called complete closure of the Cloud/Universal-Transputer and FPGA programme.

The personal browser provides access; the repository carries state-bound context; the terminal mediates tasks and readbacks. OAuth/SSO and biometrics belong to the desired product profile. The source evidence does not contain complete end-to-end acceptance of this authentication chain. A login concept must therefore not be presented as a completed biometric product binding.

A concrete startup dependency

On Main 8153c4e6..., read by the source report, RUNTIME_DEPENDENCY_MANIFEST.json still requires a Windows x64 Python runtime, an active download-consent path and bundled_windows_python_runtime=false. The document is classified as mutable, historically generated runtime state. It establishes its manifest content, not inspection

of every possible delivery archive. [R12]

For a reliable offline or self-provisioned start, the existing runtime/cache path must bind exact payload, hash, license, provenance, restore recipe and self-test. The path is accepted only when the declared environment starts without an unbound surprise dependency. General permission to assimilate does not replace this individual check.

Governance is part of delivery

In the source report, PR #449 still documents missing effective Main protection and no independent Code-Owner review. The separately read review-execution status on that PR-447 head also failed although CI and other workflows could succeed. There is no contradiction: an observer can fulfill its observation task while finding missing approval. [R9,R13]

Hardware remains a separate milestone

VHDL, synthesis, bitstream, programming and physical measurement are different acceptance steps. The supplied history records open board, programmer and physical readbacks. This edition observes no new board run. Neither a hardware date calculated from software CI nor a successful physical signal witness is claimed. [L4]

09 / FROM TASK TO DELIVERY

The sequence follows blockers.

The delta principle should reduce needless repetition. It removes neither global tests nor external dependencies. The next productive action must address the actual bottleneck.

P0: Close shared bottlenecks

First establish the authorized Authority reading path and effective repository governance. They remain two separate subjects. A token permitted to read source bytes does not automatically grant administrative rights. Protected Main does not supply missing Authority credentials either.

The concrete access check is: an already authorized credential is actually delivered through the existing bounded path to the correct runner; current Authority head and tree are then read and bound to source, run and role. The diagnostic result in the source shows only that delivery is not established in the observed process. It proves neither general absence of credentials nor the cause of a public 404 response. [R3]

Governance requires observed protection, an appropriate independent review decision and current gates. Only then is separate, expected-head-bound adoption of a candidate admissible. General Owner agreement does not replace the technical check of that particular transition. [R9,R13]

P1: Close one complete user path

Next execute a finite pilot task through personal access: record the task, admit the action, use a program or service, save the result, interrupt, restart and continue the same task correctly. Every required tool and runtime must be bound in the existing cache/provision contract. A client must be able to reconstruct the result without another improvised dialogue step. [R1,R5,R12]

For Windows x64 this test takes place on the actually required Windows 11 client. A successful ARM64 path and server x64 run are useful evidence but not substitute platforms. A separately bounded Linux pilot may be possible earlier; its scope must remain explicit relative to missing Windows or hardware acceptance. [R6]

P2: Optimize after full correctness

Correct the measurement method according to the audit. Then compare identical tasks without and with delta

reuse. Mandatory gates stay equal; result quality and error rate must not deteriorate. Adopt a speed change as a benefit only when supported within the agreed measurement window and regression budget.

An optimization can be slower yet detect errors better. Quality and time objectives must therefore be reported separately. Conversely, a fast run without full readback is not success.

P3: Make findings broadly usable

Only checked changes are integrated into existing runtime, handoff and publication paths. A successor receives its own subject binding. Older PRs are assessed against their intended effect; a subject already completed elsewhere can be classified as superseded, but not solely because of age.

The task “on every node” requires a current finite list of authorized targets. For each target, record delivery identity, local adoption and readback. A rule for future nodes does not show that all current nodes have been reached. Neither a global scan nor unauthorized self-propagation follows.

Check what defines completion

A global mandatory check can reevaluate the entire relevant state despite a small delta. It is not algorithmic waste when required for the current claim. Repeated navigation, needless reconstruction of stable relationships and duplicates of the same work unit are avoidable instead.

What the source edition actually applied

Existing sources and layout methods were reused; old and current heads were separated; calculations were checked; two methodological errors were locally demonstrated; access, governance and measurement repair were added to the forecast. No production deployment, Main merge or unmeasured performance gain follows. This English successor adds translation and new artifact validation, not new historical trials.

10 / THE TIME FORECAST

A first delivery may be near. Overall completion has no date.

A date is meaningful only when the product, acceptance scope and prerequisites actually available by then are clear.

Changes from the earlier forecast in the source report

The earlier CI-admission blocker at `e7e8737f...` no longer describes the aggregate state reported by the source. PR #447 is at `a31ebb7e...`; its CI and A/B diagnostic ran. PR #443 carries bounded positive scaling evidence. PR #437 clarified seed discovery, and #449 has a governance successor with fresh tests. [R2-R4,R7,R9]

Publication is also more than “one approval away”: the v2 contract has a documented hash/authorization transition boundary; the v3 proposal has not been activated for production. The live measurement path needs methodological work too. These points extend or structure the critical path even if individual tests are already green. [R10,R11,R14]

Why 2.5 times faster is not 2.5 times earlier

Let p be the proportion of total time affected by local speedup s . Without additional overhead, arithmetic gives

$$S_{\text{gesamt}} = \frac{1}{(1-p) + p/s}.$$

The subscript denotes overall speedup. Additional normalized effort h adds to the denominator. For $s = 2.5$ and $p = 0.1$, only 1.064 times overall speedup or six percent time savings would be possible. For $p = 0.5$, it would be 1.429 times or 30%. These are calculation scenarios; the actual p for the delivery pipeline was not measured. [C1]

Waiting for devices, access, review or external acceptance is not automatically shortened. Parallel work is also limited by runners, independent reviewers, single writers and the productive action path. Freely assuming

unlimited capacity would make the forecast unusable.

A checkable scheduling model

For work unit i , let r_i be the earliest availability of prerequisites, d_i estimated active duration and P_i its predecessors. A planning model is:

$$EF_i = \max(r_i, \max_{j \in P_i} EF_j) + d_i.$$

If no date exists for necessary access, r_i is unknown. There is then no justified fixed completion date. This names a dependency rather than making a blanket claim that engineering is inherently unpredictable.

Assumptions of the following window

The calendar on the next page is an **editorial engineering estimate**, not a forecast fitted to measurements. It assumes an available executor, reachable independent reviewer, required runners/devices, no newly discovered severe defects and at most one normal correction cycle per package.

T_0 is not the time of agreement in chat. It is the actually observed time at which the respective prerequisites become available. Neither daily throughput nor success probability is invented. “Days” means elapsed processing days with active work under this capacity assumption; inactivity shifts the calculation.

The concrete answer within the historical scenario

A narrowly bounded software pilot appears plannable over a few days to about a week under these assumptions. The evidence provides no responsible completion date for the entire system including SSO/biometrics, all nodes and physical FPGA acceptance.

10 / CONDITIONAL CALENDAR PLANNING

What can be accepted, and when.

Calculation example: Required prerequisites are actually available on **4 October 2026**. This premise was **not satisfied** in the source report's readback. These windows show consequences of that preserved scenario, not promised dates or new present-state observations.

Milestone	Active time remaining	Example calendar	Acceptance / dependency
Bounded Authority read path	0.5–1 day after actual delivery	4–5 October	Credential reaches correct runner; current HEAD/TREE readback. No expansion of rights.
Corrected A/B trial	1–3 days after access and test environment	5–7 October	Equal byte/mode definitions, full timing boundary, controlled AB/BA pairs and accepted readback.
Governance/recovery candidate effective	1–3 days after protection and review	5–7 October	Separate promotion, new Main binding, first actual recovery/lifecycle effect.
Bound Windows runtime	1–2 days after available payload and adapter path	5–6 October	Version/hash/license/provenance, restore and startup test. No unplanned download.
Windows 11 AMD64 witness	1–3 days after suitable client	5–7 October	Native architecture, persistent state, interruption/restart, replay refusal and public readback.
Actual task continuity	2–5 days after productive handoff	6–9 October	Intervening question and client interruption without Owner restart; no duplicate external effect.
Bounded personal pilot	3–7 days after all pilot prerequisites	7–11 October	One continuous publicly reachable user path, documented platform scope and fresh acceptance.
Zenodo complete edition	1–3 days after contract and fileset closure	Earliest 5–7 October in the full-readiness scenario	Activated valid publisher contract, new return, exact single-use decision, identical uploaded bytes and redownload.
IETF companion / arXiv	Preparation: days; acceptance open	No acceptance date	Validation and complete sources; actual submission separate.
SSO/biometrics, all nodes, complete FPGA objective	No supported remaining duration	Open	Missing implementation/carrier/integration and end-to-end evidence for each.

Do not add incompatible time gains

Local factors 2.5, 1.624 and 2.141 arise from different subjects. They are neither multiplied together nor transferred to the entire roadmap. The pilot calendar applies only to a predetermined scope. Unavailable access still has no automatic provisioning date.

The next supported forecast arises once actual approval, runner, handoff and measurement times are recorded. Observed durations then replace particular assumptions; remaining variation must be preserved. A negative trial may lengthen the estimate, a reproducibly smaller delta may shorten it.

11 / PUBLICATION

A publishable document is not yet a published result.

Repository, Zenodo, IETF, arXiv and Wikipedia have different purposes and acceptance boundaries. They are not collapsed into one “published” status.

The new scientific edition described by the source

The complete edition is a new candidate with new bytes, extended methodological findings and a new forecast. It does not silently replace a previously authorized PDF. Text sources, calculation artifacts, claim register and change notice accompany the PDF. The layout template remains a design source, not substantive peer review. This English successor is separately identified again.

The edition carries no unfulfilled kernel classification. New formal statements specify model, assumptions and argument; no machine proof is claimed. Document QA checks bindings, calculations, coverage and presentation, not the truth of the entire external world.

The active Zenodo boundary in the source report

The v2 policy requires exact candidate bytes, complete claim disposition, appropriate evidence, boundary tests, return delivery and then a candidate-specific single-use decision. After the effect, it requires public record verification, byte-identical redownload and repository persistence. A general “approval granted” does not replace the later exact-byte decision. [R10]

The v3 proposal prepared at `a31ebb7e...` separates immutable proof readiness from later upload authorization. It addresses the documented conflict in which the earlier bundle includes an authorization field whose change changes the hash to be authorized. The proposal leaves active v1/v2 contracts and the production publisher unchanged. It is expressly *not activated*. The binding final appendix preserves the later, separately identified implementation disposition without rewriting this historical statement. [R14]

Thus no apparently final `AUTHORIZE_EXACT_UPLOAD` line is generated for the complete edition while the valid production contract, complete binding and actually executable path remain open. No token, authorization or upload is invented.

ietf: protocol semantics, not consciousness certification

The public Datatracker readback in the source report lists individual Experimental draft `draft-lohmann-qikvrt-effect-ack-03`. Its existing core does not require another wire format solely because of a new philosophical interpretation. A separate epistemic-status profile is a useful working candidate but needs its own specification and validation. Internet-Draft, RFC and IETF consensus are distinct. [W1,L4]

arXiv and Wikipedia

arXiv provides scientific submission and distribution. Registration, endorsement where required, complete source materials and moderation are separate prerequisites. Moderation is not peer review; no arXiv publication is claimed here. The English successor supplies the complete English text required by the documented language correction, without submission. [W6]

Wikipedia should not establish a new discovery through self-publication. The prepared path described by the source is a neutral draft with disclosed conflict of interest and assessment of independent coverage. That edition performed no comprehensive new notability search and claims neither established significance nor established insignificance. [L4]

Preservation is a technical obligation

Versioned sources, multiple authorized storage locations, checksums and restore tests reduce loss risk. They do not logically guarantee that data can never be lost. A hash does not replace a copy; a copy does not replace a recovery test; a node-inheritance rule does not replace actual readback on every node.

Document delivery, not platform completion

The source edition supplies a research article, an accessible synthesis and checkable companion artifacts. This succes-

sor supplies their complete English manuscript translation with new bindings. Zenodo publication, Main integration, node replication and product release remain separate effects with their own evidence.

APPENDIX A / CLAIM REGISTER

A claim remains separate from its verification.

This register classifies the principal statements of the complete synthesis. It is an editorial disposition, not an already production-validated machine-proof bundle or upload authorization.

Historical register and binding disposition

This table translates the original editorial register, including its open question formulations and historical use of “current”. The final staging appendix retains the later binding disposition of all 30 claims and clarifies C18/C19/C21/C24/C27/C28/C30. An OPEN row is not an affirmative finding. Neither table transfers predecessor tests or acceptance to this successor.

ID	Statement and scope	Class	Binding / open evidence
C01	QIK-VRT is described as a complete system, not a single model.	NORMATIVE	R1; system boundary used here.
C02	Purpose, reuse and continuous improvement are documented in the endpoint.	SOURCE_BOUND	R1; document presence is no overall execution proof.
C03	Means may change while a contract core should remain preserved.	NORMATIVE	R1; concrete transition invariants needed.
C04	Inductive invariant preservation holds under initial and transition premises.	INTERPRETATIVE	Theoretical derivation; kernel check open.
C05	Universal error-free truthfulness enforcement is not established.	OPEN	Full path control and semantic validators lack aggregate evidence.
C06	EFFECT_ACK-DONE in the I-D permits release before an effect; it is not automatic execution.	SOURCE_BOUND	W1; product completion separate.
C07	Hash binding is neither authentication nor proof of the source.	INTERPRETATIVE	Technical interpretation under cryptographic assumptions.
C08	Earlier evidence must not silently accept successors.	NORMATIVE	R1, R10.
C09	A wrapper exists under given computable adapters and checkers.	INTERPRETATIVE	Construction; machine verification open.
C10	Complete observability and arbitrary reachability do not follow.	INTERPRETATIVE	Model counterexample arguments.
C11	Black-box integration does not guarantee complete identification.	INTERPRETATIVE	Finite observation remains bounded.
C12	Functional consciousness is a defined target profile.	NORMATIVE	Definition, not empirical satisfaction.
C13	Complete satisfaction / phenomenal experience of QIK-VRT.	OPEN	Separate assessment required.
C14	Two nodes do not establish methodological independence.	INTERPRETATIVE	Analysis of roles and dependencies.
C15	Nine microbenchmark medians are reproducible from existing raw numbers.	EMPIRICALLY_EVIDENCED	L3, C1; data/arithmetic check, not timing replication.
C16	Historical structural ratio: $3,928/20 = 196.4$.	SOURCE_BOUND	L4 and C1; no new runtime measurement.
C17	Bounded $1/2/4$ -process speedup is documented.	SOURCE_BOUND	R4; original trial archives not fully rechecked here.

ID	Statement and scope	Class	Binding / open evidence
C18	A/B diagnostic at the source time has credential-delivery HOLD.	SOURCE_BOUND	R3; actual job log at a31ebb7e.
C19	Measurement code at the source time starts timers after retrieval.	SOURCE_BOUND	R11; static methodological finding.
C20	Text decoding/binary data and mode comparison are not equivalent.	EMPIRICALLY_EVIDENCED	C1; two isolated local controls.
C21	Full distributed speedup is measured.	OPEN	No admissible positive claim.
C22	PRs #437/#448/#449 have new candidates with documented tests.	SOURCE_BOUND	R7–R9; no Main adoption.
C23	Windows 11 AMD64 acceptance and actual interruption remain open.	SOURCE_BOUND	R5, R6.
C24	Main runtime manifest reports no bundled Windows Python runtime.	SOURCE_BOUND	R12; source-time file content, not full release audit.
C25	Time model and calendar windows.	INTERPRETATIVE	Conditional editorial engineering estimate, not statistical forecast.
C26	A 2.5 local factor is not 2.5 times overall duration.	INTERPRETATIVE	C1; explicit proportion calculation.
C27	The v3 publication contract is a proposal not activated for production.	SOURCE_BOUND	R14; active production remains v2.
C28	This new PDF is already published on Zenodo / all nodes.	OPEN	Not asserted; no corresponding effect executed.
C29	Historical significance of the discovery.	INTERPRETATIVE	Originator assessment, not measured fact.
C30	“Never lose it again” is guaranteed.	OPEN	No absolute guarantee; replication and restore tests needed.

The complete machine-readable companion also contains source paths, scope limits and mapping to accessible prose. This register claims no already executed production v2/v3 validation. New `FORMAL_PROVED` claims without kernel receipts were expressly avoided.

APPENDIX B / VISIBLE CLARIFICATIONS

History is preserved. Status is corrected.

These changes belong to the return delivery. Historical files are not rewritten or reused as present results.

1. Contract and execution proof

Earlier versions used “proved” and “enforced” for the general truthfulness invariant. Correctly: the rule is formulated and materialized in the project as an objective or contract. The evidence does not demonstrate universal bypass-free enforcement of all free-form statements. C04/C05 therefore distinguish model argument, normative objective and implementation evidence.

2. Meaning of `EFFECT_ACK`

The original prose often uses effect acknowledgement as final confirmation after the effect. The public I-D instead describes an authorization boundary before a

downstream effect. Both can be useful in a larger chain but require different names and checks. This edition separates Gate-DONE and Task-DONE.

3. Integration theorem

The wrapper construction states explicit assumptions. It establishes neither complete internal state preservation under lossy observation nor guaranteed arbitrary reachability. The old `FORMAL_PROVED` label is not adopted as current evidence without a kernel receipt.

4. Comparison count, time and knowledge

99% fewer key comparisons do not mean 99% less total runtime. 196.4:1 is a structural ratio of historical files

and selected deltas. The actual microbenchmark includes initialization and sorting. “Provenance-bound memory” there interprets the delta idea rather than independently measuring complete provenance validation.

5. Live experiment

The earlier assertion that only one carrier remained is supplemented by the methodological finding. Existing code measures locally after download. Binary data, Git modes and the complete time boundary require correction for the stronger claim. Isolated controls document reproducible counterexamples.

6. The actual new parallel measurement

PR-443 documentation at the source time contains positive 1/2/4-process results within the stated host/load scope. The earlier blanket description “scaling open” was incomplete for that trial. Causal explanation of earlier variation and generalization across runners remain open.

7. Dates and roadmap

Earlier windows such as “hours to one day” are not carried forward as measurements. Access, governance, measurement correction and final fileset are explicit prerequisites. Local speedup is not transferred to physical, administrative or editorial waiting times.

8. Capabilities and undecidability

The task is not represented as “solve every solvable problem reliably and without limits”. A problem may be computable yet exceed available time, resources, observation or permissions. A universal control wrapper does not imply general semantic decidability of arbitrary programs; classical undecidability results remain relevant. [W7]

Preservation without epistemic inflation

The supplied original texts, historical microbenchmark file and layout source remain byte-identical in their source archive. The new synthesis preserves their themes while stating the source-time evidence status and clarifications. “Every bit” also means not quietly treating an old assertion as a present proof. English translation preserves that boundary.

APPENDIX C / SOURCES AND PROVENANCE

What supports this edition.

Local inputs, repository sources freshly read for the source report, checked job outputs, external primary literature and calculations are separate source classes. All repository reads listed here occurred on 3 October 2026. This English translation does not repeat those historical observations.

Supplied sources

L1. *QIKVRT_SINN_UND_ZWECK(4).pdf*, 26 pages. Used as layout and epistemic reference. SHA-256: 6a15c71919a6c703cfeabfa3e1e13d9d1928c2a9accdfc333aef807c267f31ca. Complete file in the original local source archive.

L2. *Das unterscheidet QIK-VRT!.txt*. Source prose about intention, execution, effect, observation, acceptance, bit binding, self-reference and limits.

L3. *qikvrt_collective_cognition_ab_microbenchmark_20261003.json*. Original nine configurations with seven raw values per arm. Calculations of the source edition

C1. [RECALCULATIONS_AND_METHOD_CONTROLS.json](#) and [calculate.py](#): nine recalculated median pairs, ratios of documented Linux medians, four proportion scenarios and two isolated methodological counterexamples. No remote mutation or general formal proof. These are historical source-edition computations, not new translation-time trials.

Glossary

Claim: a bounded statement with explicit status.

Readback: reobservation of relevant state.

Provenance: traceable origin and state attribution.

Exact Head/Tree: a particular Git commit or content tree. **Carrier:** an actually available executor or callable

access path. **HOLD:** an unmet prerequisite, not invented success. **TCB:** the trusted implementation base on whose correct operation a safety claim depends.

T_0 : observed availability of the respective planning prerequisites, not merely authorization wording.

Verification notice and scope

Technical formulas are conditional derivations; statement groups are classified; raw numbers were recalculated in the source edition. Layout QA and file hashes are recorded for the finished successor PDF in separate manifests. No self-reference to this PDF's own

file hash is invented inside it.

The design follows the existing *Sinn und Zweck* template: dark editorial cover, serif/sans hierarchy, two-column text, colored evidence boundaries, glossary and sources. The portable staging edition uses Latin Modern filename-based fonts. Font binaries are not in

the source package.

Closing principle

QIK-VRT should grow through preserved knowledge and actually completed tasks. The invariant core gains practical value where a human can inspect the effect.

Source state and claim boundaries

This English translation is a new, unsubmitted review candidate. It preserves the historical complete edition and its explicitly bounded claim disposition.

Binding reading

The body reports the frozen source state of 3 October 2026. Terms such as current and Draft are historical statements at their respective source times. No present repository, PR, runtime or publication state follows from typesetting or translation alone. The original PDF and 36-file ZIP, and the German staging package, remain unchanged. This PDF inherits no upload authorization. The following matrix reports the existing disposition. It claims neither new replication of historical trials nor full semantic verification of every natural-language sentence. For every row, the original PDF and prose are a frozen editorial state; the machine-readable disposition and METHOD_CLAIM_BOUNDARIES.md refine its scope. No full semantic verification of all natural-language statements is claimed. No claim is FORMAL_PROVED. Normative contracts are not universal execution proofs. A new author decision, destination metadata and action-time upload decision remain separate requirements. The unchanged German CLAIM_MATRIX.json supplies frozen identities, scopes and evidence; the English claim correspondence separately binds the translation.

ID	Epistemic status	Bound statement and scope
C01	NORMATIVE	QIK-VRT is described as a complete system, not a single model. Scope: R1; system boundary used here.
C02	SOURCE_BOUND	Purpose, reuse and continuous improvement are documented in the entrypt. Scope: R1; document presence is not proof of complete execution.
C03	NORMATIVE	Means may change while a contract core should remain preserved. Scope: R1; concrete transition invariants are needed.
C04	INTERPRETATIVE	Inductive invariant preservation holds under initial and transition premises. Scope: Theoretical derivation; kernel verification remains open.
C05	OPEN	Universal error-free truthfulness enforcement is not established. Scope: Complete path control and semantic validators are missing as an overall demonstration.
C06	SOURCE_BOUND	EFFECT_ACK-DONE in the I-D permits release before an effect; it does not automatically establish execution. Scope: W1; product completion is separate.
C07	INTERPRETATIVE	Hash binding is neither authentication nor proof of the source. Scope: Technical interpretation under cryptographic assumptions.
C08	NORMATIVE	Earlier evidence must not silently accept successors. Scope: R1, R10.
C09	INTERPRETATIVE	A wrapper exists under given computable adapters and checkers. Scope: Construction; machine verification remains open.
C10	INTERPRETATIVE	Complete observability and arbitrary target reachability do not follow. Scope: Counterexample arguments within the model.
C11	INTERPRETATIVE	Black-box integration does not guarantee complete identification. Scope: Finite observation remains bounded.
C12	NORMATIVE	Functional consciousness is a defined target profile. Scope: Definition, not empirical satisfaction.
C13	OPEN	Complete satisfaction / phenomenal experience of QIK-VRT. Scope: A separate assessment is required.
C14	INTERPRETATIVE	Two nodes do not prove methodological independence. Scope: Analysis of roles and dependencies.
C15	EMPIRICALLY_EVIDENCED	Nine microbenchmark medians are reproducible from existing raw numbers. Scope: L3, C1; data and arithmetic checking, not replication of the timing experiment.

ID	Epistemic status	Bound statement and scope
C16	SOURCE_BOUND	Historical structural ratio: 3,928/20 = 196.4. <i>Scope:</i> L4 and C1; no new runtime measurement.
C17	SOURCE_BOUND	Bounded 1/2/4-process speedup is documented. <i>Scope:</i> R4; the original trial archives were not completely checked again here.
C18	SOURCE_BOUND	The archived A/B diagnostic at a31ebb7e documents credential-delivery HOLD. <i>Scope:</i> Historical run 37128318275 / job 111218106133; no current integration evidence and no speedup.
C19	SOURCE_BOUND	The archived measurement code starts timers only after repository retrieval. <i>Scope:</i> Exact historical blob acafd1ae37dcb9ffcab371fa79e3e874cfe83b91; local comparisons, not a distributed mutation/reconciliation/readback cycle.
C20	EMPIRICALLY_EVIDENCED	Text decoding/binary data and mode comparison are not equivalent. <i>Scope:</i> C1; two isolated local controls.
C21	OPEN	Full distributed speedup remains unestablished. <i>Scope:</i> OPEN: no admissible positive claim from the microbenchmark, structural ratio or successful diagnostic workflow.
C22	SOURCE_BOUND	PRs #437/#448/#449 have new candidates with documented tests. <i>Scope:</i> R7–R9; no Main adoption.
C23	SOURCE_BOUND	Windows 11 AMD64 acceptance and actual interruption remain open. <i>Scope:</i> R5, R6.
C24	SOURCE_BOUND	The runtime manifest on archived Main reports no bundled Windows Python runtime. <i>Scope:</i> Historical Main 8153c4e69a6245aadf67f0741fb50d9707c19e34 / blob bd2b893176d93814f38d024b5a095b770eee2aa3; no statement about later runtime candidates.
C25	INTERPRETATIVE	Time model and calendar windows. <i>Scope:</i> An editorial conditional engineering estimate; not a statistical forecast.
C26	INTERPRETATIVE	A 2.5 local factor is not a 2.5 overall-duration factor. <i>Scope:</i> C1; explicit proportion calculation.
C27	SOURCE_BOUND	The v3 path is technically implemented and checked but barred from production without detached contract activation. <i>Scope:</i> Integration input 80e34e4d; unchanged v1/v2 contracts; REVIEW_REQUIRED. Technical readiness grants neither production activation nor AUTHORIZE_EXACT_UPLOAD.
C28	OPEN	Zenodo publication and replication of the complete edition on all nodes are not established. <i>Scope:</i> OPEN: repository materialization in a Draft PR is not a Zenodo effect, Main promotion or all-node acceptance.
C29	INTERPRETATIVE	Historical significance of the discovery. <i>Scope:</i> Originator assessment, not a measured fact.
C30	OPEN	An absolute guarantee never to lose content again is not established. <i>Scope:</i> OPEN: hash binding and repository persistence do not replace independent replication and restore tests.

Preserved methodological clarifications

C18

The archived A/B diagnostic at a31ebb7e documents credential-delivery HOLD.

Historical run 37128318275 / job 111218106133; no current integration evidence and no speedup.

Reason for the original clarification: bind the historical credential HOLD to its original run/HEAD/TREE subject.

C19

The archived measurement code starts timers only after repository retrieval.

Exact historical blob acafd1ae37dcb9ffcab371fa79e3e874cfe83b91; local comparisons, not a distributed mutation/reconciliation/readback cycle.

Reason: limit timer, binary-path and Git-mode findings to the specific inspected source.

C21

Full distributed speedup remains unestablished.

OPEN: no admissible positive claim from microbenchmark, structural ratio or successful diagnostic workflow.

Reason: explicitly state that the open distributed speedup has not been established.

C24

The runtime manifest on archived Main reports no bundled Windows Python runtime.

Historical Main 8153c4e69a6245aadf67f0741fb50d9707c19e34 / blob bd2b893176d93814f38d024b5a095b770eee2aa3; no statement about later runtime candidates.

Reason: bind runtime state as a historical file observation rather than a moving current state.

C27

The v3 path is technically implemented and checked but barred from production without detached contract activation.

Integration input 80e34e4d; unchanged v1/v2 contracts; REVIEW_REQUIRED. Technical readiness grants neither production activation nor AUTHORIZE_EXACT_UPLOAD.

Reason: separate intervening v3 implementation from production activation and later single-use authorization.

C28

Zenodo publication and replication of the complete edition on all nodes are not established.

OPEN: repository materialization in a Draft PR is not a Zenodo effect, Main promotion or all-node acceptance.

Reason: separate repository adoption from Zenodo publication and replication acceptance.

C30

An absolute guarantee never to lose content again is not established.

OPEN: hash binding and repository persistence do not replace independent replication and restore tests.

Reason: mark absolute losslessness as an open guarantee.

Further preserved limits: truthfulness is a normative contract, not a universal execution proof. Conditional invariant and wrapper arguments are INTERPRETATIVE; no claim is FORMAL_PROVED. EFFECT_ACK before an effect stays separate from subsequent task acceptance. C15 recalculates nine existing number series without repeating timing trials. C17 reports only documented 1/2/4-process medians 0.349138 / 0.214989 / 0.163044 seconds; ratios 1.623981 and 2.141373 are calculations, not new trial replications. C20 reproduces only two isolated methodological controls. C25/C26 are conditional engineering scenarios starting at actual prerequisite availability T_0 ; 7–11 October is not a delivery promise. Subjective experience, global system acceptance, SSO/biometrics, physical FPGA execution and methodologically independent scaling are not confirmed.

The original editorial proof/return DRAFTS in the ZIP and original-review are historical documents and must not authorize production. Normative disposition of the original adoption: CLAIM_MATRIX.json, MACHINE_PROOF_BUNDLE.json and PREPUBLICATION_RETURN_RECEIPT.json in the frozen source. Production activation and a later single-use AUTHORIZE_EXACT_UPLOAD decision are detached and remain absent. This English staging manifest and return receipt identify new bytes and grant no upload authority.

Intervening methodological successor

During the original adoption, a6f930bb9c8bad58a10d17cd10c87d94c38f0b25 / tree fbfd9a90e086128b5acd4ce5602f0abefed8fce4 WAS materialized as a separate methodological repair candidate. Its measurement code, blob 0d8e10d419e453a832453343b8a82b330193c330, uses raw bytes and NUL-delimited paths, checks Git mode/type/object/content and separates local comparison costs from the full remote-fetch/isolated-replica-reconciliation/fresh-readback cycle. Reconciliation changes only the local disposable replica. It does not mutate either production remote and does not prove distributed production speedup. Historical C18/C19 findings in the original PDF are not rewritten; fresh technical checking must execute the integrated successor. Translation does not claim to rerun that historical experiment.
